

Title slide for use with Transportation work stream

1. Both at some point were sent to work at Hertfordshire County Council in UK
2. Return to NZ. Providing remote assistance from Hamilton

• Hertfordshire

- Located immediately north of London
- 5000 km highway network
- Population approx. 1.2 million
- County town = Hertford (pop 26 k)
- Largest city = Watford (pop 96 k)
- 10 districts in County

SaferRoads Conference 2017 | opusinternational.com

Some details about Hertfordshire to set the scene.

· Hertfordshire (old infrastructure)

- Welwyn Viaduct
- 475 m long and 30 m high
- Opened in 1850 by Queen Victoria who was frightened to travel on it because of its height

SaferRoads Conference 2017 | opusinternational.com

Briefly - setting the scene

- **Hertfordshire (really old infrastructure)**

- Hatfield House: effectively Queen Elizabeth I was kept under house arrest at Hatfield by Queen Mary until her ascension to the throne in 1558

SaferRoads Conference 2017 | opusinternational.com

Briefly - setting the scene

• Hertfordshire (really, really old infrastructure)

- Roman Roads.
Watling Street, Elstree
- Constructed about 43
- 410 AD
- What is the design life
of roads in your
jurisdiction?

SaferRoads Conference 2017 | opusinternational.com

Briefly - setting the scene.
Interesting the infrastructure design life.

· Hertfordshire (really, really “old” infrastructure)

- Roman Roads.
Watling Street, Elstree
- A5183

SaferRoads Conference 2017 | opusinternational.com

Briefly - setting the scene.
Example of what the Roman Road looks like today.

• Overview

- Why bother?
- Engineering
- GIS
- Quite a few slides, but survivable

SaferRoads Conference 2017 | opusinternational.com

Now let's get down to business

· **Key messages**

- Skid resistance is an important road safety measure
- One size does not fit all, have a skid resistance strategy that fits your network
- Creating and applying a bespoke skid resistance strategy takes a bit of effort, but it is achievable

• Why bother?

- Hertfordshire already has a relatively safe road network:
 - United Kingdom one of safest road networks
 - Hertfordshire performs better than average in UK for KSI
- Skid resistance an important road safety measure
- Are road deaths and serious injuries acceptable?
- We've got all this data, now what?
- Hertfordshire network compared with Highways England
 - Skid resistance strategy can be flexible and fit for purpose

· **Fundamental aims**

- Engineering components of strategy address:
 - What is skid resistance?
 - How to measure skid resistance
 - Approach used in Hertfordshire

• Budgets

- Always budget limitations
- Prioritise spending
 - Road hierarchy A, B, C, and U
 - Higher risk
- Road users know the road hierarchy

SaferRoads Conference 2017 | opusinternational.com

Map done by Renee Schicker (Opus)

- **Road hierarchy**
A-Roads

- A10, north of Ware

SaferRoads Conference 2017 | opusinternational.com

Example of an A Road

- **Road hierarchy**
A-Roads

- A505, Hitchin

SaferRoads Conference 2017 | opusinternational.com

Another A road example

- **Road hierarchy**
B-Roads

- B656, Baldock

SaferRoads Conference 2017 | opusinternational.com

Example of a B road

- **Road hierarchy**
B-Roads

- B1000, near Hertford

SaferRoads Conference 2017 | opusinternational.com

Another B road example

- **Road hierarchy**
C-Roads

- C21, Arlesey Road,
Ickleford

SaferRoads Conference 2017 | opusinternational.com

Example of a C road

- **Road hierarchy**
U-Roads

- 5U562, Woolgrove Road, Hitchin

SaferRoads Conference 2017 | opusinternational.com

U road example

▪ **Basis for event categories**

- Event categories based on Highways England standard
- HE has 10 site categories
- HCC has 16 site categories, including:
 - variation by speed limit
 - controlled versus uncontrolled approaches
 - lower curve radii than trunk roads
 - inclusion of U-roads

SaferRoads Conference 2017 | opusinternational.com

Points of difference and important considerations leading into the geospatial analysis.

Event categories

- Familiar, but different
- Ticked cells are the default IL values used in the GIS process

SITE CATEGORY AND DEFINITION		INVESTIGATORY LEVEL							
		0.30	0.35	0.40	0.45	0.50	0.55	0.60	0.65
Non-Event	A Motorway class	Not Applicable							
	B Dual carriageway non-event		✓						
	C Single carriageway non-event, speed limit >30 mph			✓					
	D Single carriageway non-event, speed limit ≤30 mph		✓						
Junctions	QU Across all junctions and uncontrolled approaches to junctions				✓				
	QC Controlled approaches to junctions, including approaches to roundabouts (refer endnote)					✓			
	R Roundabout circulatory carriageway				✓				
Ped Xings	K Approaches to controlled pedestrian crossings					✓			
Gradient	G1 Gradient 5-10% longer than 50 m				✓				
	G2 Gradient ≥10% longer than 50 m					✓			
Curves	S1 Bend radius ≤500 m – dual carriageway				✓				
	S2 Bend radius ≥250 m and <500 m – single carriageway					✓			
	S3 Bend radius <250 m – single carriageway						✓		
Non-Event	U1 Unclassified road with speed limit ≤30 mph	0.35 for all locations except where site categories QC, K, and/or US apply							
	U2 Unclassified road with speed limit >30 mph	0.40 for all locations except where site categories QC, K, and/or US apply							
	US Unclassified Specific; IL site on unclassified road for which specific intervention level has been set	IL will be determined from risk analysis for site, based on site categories above.							

SaferRoads Conference 2017 | opusinternational.com

✓ VALUE APPLIED IN MODEL

This table from the Hertfordshire County Council Skid Resistance Strategy has been central to what the automated spatial analysis is to achieve. The site categories and their criteria in defining them as well as what IL value to apply based on site category identified. The coloured boxes indicate the separate model streams before everything is compiled together.

• Length of demand

- Stopping distance varies based on speed
- But, most standards have "standard" length of about 50 m
- HCC lengths vary from 25 m (30 mph) to 130 m (70 mph)

Source: Cenek and Brown

SaferRoads Conference 2017 | opusinternational.com

Stopping distance, important to cover this as lengths based on speed limit are a factor in the approach to junctions and pedestrian crossings.

• **Curves**

- “Safer Roads” more important to road users than any other transport services
- Road users need appropriate skid resistance
- Road users don't know curve radii
- Allow for variation in measured radius for assigning curve IL
- Contiguous varying curves treated as a complete curve

SaferRoads Conference 2017 | opusinternational.com

Road users don't know the curve radii and generally wouldn't care.
Not much signage for curves unless really problematic.

· **Prioritisation: the next chapter**

- Prioritisation process (to be tested):
 - Amount skid resistance below IL
 - Personal injury collision (PIC) history
 - Highway classification
 - Speed limit
 - Normalised by length

· **Engineering summary**

- Strategy to identify risk and prioritise spending
- Skid resistance fit for County's purposes
- Skid resistance to meet road user demand
- Rely on GIS magic to make it work

· Applying the strategy to the network

SaferRoads Conference 2017 | opusinternational.com

Segway from strategy into applying it in GIS.

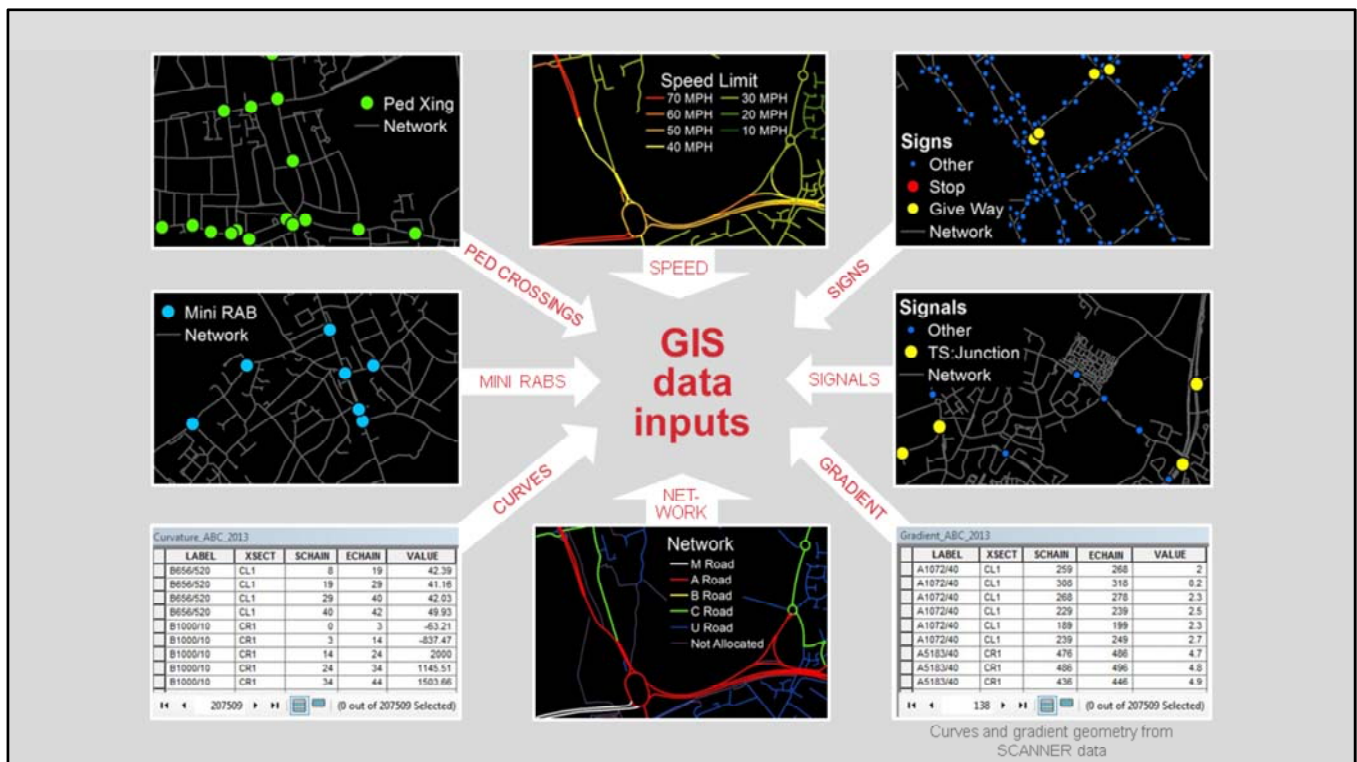

Combine GIS knowledge, software, and data to develop a process that will generate an output of a classified network.

Why develop models? Record process, easier to review process, can re-run, hit play and walk away.

Refinement: covers issues with the input data where it needs improving; learning through multiple failures and gradual successes with each hurdle and identifying where else this can be applied or a change in the order of operations; where criteria in the strategy doesn't cover all cases (i.e. the model output has raised some odd trends which can be explained based on the process and data) and it raises a point of what do we do in this case? Prompting discussion & brainstorming and documentation in the strategy to cover those instances.

Resulting output should assist in identifying which sites have higher or lower ILs and where measured skid resistance is below IL.

This project has been 100% remote GIS input, working from NZ but in collaboration and discussion with Rob and the guys in the UK team.

Raw input data as provided by HCC (UK).

Additional (more detailed) info:

- **Network** dataset: base network with a range of information about the individual roads. Includes FEATURE_ID (unique road name e.g. A1000/100), ROADTYPE (e.g. Single 2 lane carriageway, Roundabout, Dual Carriageway, etc.), CUSTOMER (i.e. who is responsible for maintaining that road), and various others
- **Speed** dataset: no useful attributes other than speed limit. Makes it a bit more tricky to identify which road ID has what speed limit, but can be done.
- **Curve** and **Gradient** tables – contain geometry data captured in the SCANNER data. LABEL matches the FEATURE_ID field in the Network dataset (so can linear reference by matching ID); XSECT (direction increasing/decreasing or in this case CL1/CR1); SCHAIN (starting route position/chainage in metres. Used in linear referencing to define start of extent along the route ID); ECHAIN (end route position/chainage in metres, used in linear referencing to define end of extent along the route ID); VALUE (curve radius for curve, gradient value for gradient).
- **Mini RAB** – point locations of the mini roundabouts on the network (and some outside the network). Factor involved in junctions modelling.

- **Signals** – all signal types across the network represented as points. Traffic signals (TS: Junction) are just a subset of this data which feeds into the junctions modelling. One point represents a set of signals at or near a location, not individual signals.
- **Signs** – all signs on the network. Subset of Stop and Give Way priority control related signs were extracted as a subset for use in the junctions modelling. Signs dataset includes a FEATURE_ID which matches that in the Network dataset so can identify which road the sign belongs to.
- **Pedestrian crossing** – point locations of where pedestrian crossings are. Includes some information about the type.

• Build the base road network

- Detailed network dataset (road ID e.g. A1000/10, road type, customer, etc.)
- Add direction and speed limit

SaferRoads Conference 2017 | opusinternational.com

Bringing together the information that is required in the base network which will essentially be the skeleton of the modelling process. Important to ensure the base network is set up first and has the required information for the automated spatial analysis.

While the Network dataset has most the information required, direction and speed limit are required in a number of modelling stages.

- Direction is required to differentiate between records of differing direction where these share the same centreline and as a result will result in two stacked features of differing information sharing the same exact space. The need to identify between these is crucial to avoid information from one being inadvertently added to the other through the spatial relationships. So it is a means of ensuring the data added by spatial means is done so correctly..
- Speed limit – this is used to define some site categories (i.e. non-event categories), and also approach lengths in the junctions and pedestrian crossing analyses.

Non-events

- Classify full ABCU network based on hierarchy and speed limit

Road	Site Category	
	Speed ≤ 30 mph	Speed > 30 mph
A, B, C	D	C
U	U1	U2

SaferRoads Conference 2017 | opusinternational.com

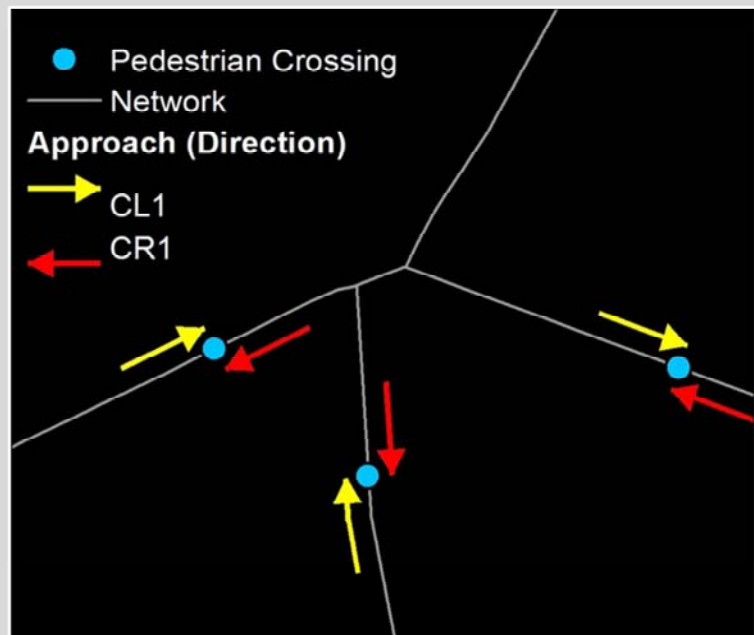

Non-Event – classify the whole network depending on whether the road is and A,B,C or U road in conjunction with what speed limit is for that road.

· Pedestrian crossings

- Locate point on network
- Determine approach length based on speed limit
- Approaches = point route position +/- approach length depending on direction

SaferRoads Conference 2017 | opusinternational.com

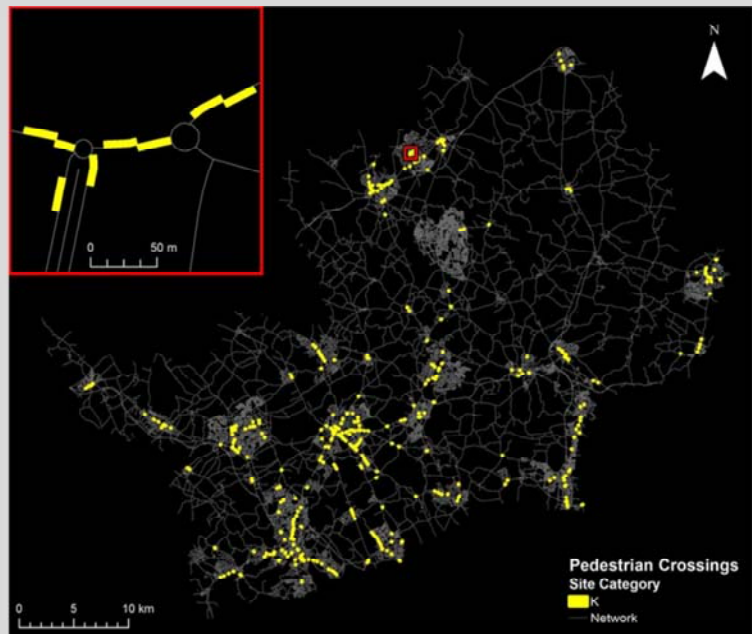

Locate the pedestrian crossing points on the network, obtaining route id and route position, use this information with the approach length based on speed limit, and direction to differentiate between approach and departure.

· Pedestrian crossings

- Approach based on direction
- Approach length based on speed limit

Speed Limit	Approach Distance
70 mph	130 m
60 mph	95 m
50 mph	70 m
40 mph	45 m
30 mph	25 m
20 mph	25 m

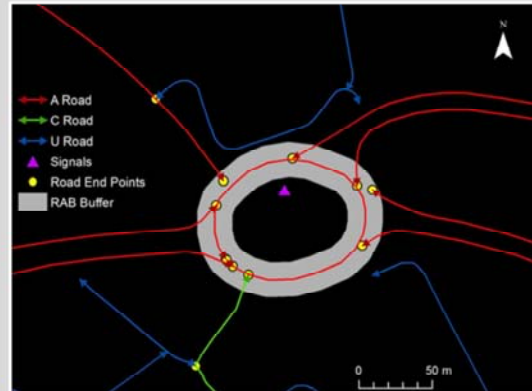

SaferRoads Conference 2017 | opusinternational.com

Some extents are shorter than they should be as a result of being located near the end of the Road ID (Feature_ID) extent. The Road ID (Feature ID) dictates which road the approach is to be drawn along, it only knows to look for the one the pedestrian crossing point was located on not the adjoining road or roads within the approach distance. So the approach doesn't extend around side roads where pedestrian crossings are near junctions.

Locating junctions

- Ends of roads, midblock, at a circulatory roundabout

SaferRoads Conference 2017 | opusinternational.com

- Similar approach to pedestrian crossings, but far more complex.
- Road “end points” based on start/end locations
- Points within ABC buffered route (did not look at junction of U roads with U roads)
- Define the junction area and identify the points and number of points within this junction area
- Exclude change in A/B/C section (presence of 2 ABCU end points of same road name e.g. A100 – if we disregard the /XXX)
- Approaches to roundabouts – identify road end points which fall within a defined zone around the roundabout centreline
- Generate points for the ABC network to represent the ABC road where a roads joins at midblock (otherwise the midblock approaches to junction are not represented).

• Types of junctions

Controlled	Uncontrolled (QU)
<ul style="list-style-type: none">• Circulatory roundabouts (R):<ul style="list-style-type: none">• Signalised• Non-signalised• Roads under priority control (QC):<ul style="list-style-type: none">• Signalised junctions• Stop/Give Way• Mini roundabouts• Approaches to roundabout• Hierarchy where no data regarding control	<ul style="list-style-type: none">• Departures from roundabouts• All other approaches to junctions

SaferRoads Conference 2017 | opusinternational.com

- Stop, give way, rotate priority, signs taken from dataset of all signs.
- Traffic signals taken as a subset of the dataset of all signals.
- Traffic signals – a single feature represent a set of traffic signals not individual traffic signals. So signalised RABs were a bit trickier as the point can be anywhere near the roundabout or located in the RAB island.
- Hierarchy: A road > B road > C road > U road

Categories R, QC, QU defined in earlier slide (22) and next slide (36).

· Junction events

Site Category	Description	IL
R	Circulatory roundabout	0.45
QC	Controlled junctions, including approaches to roundabouts	0.5
QU	Across all junctions and uncontrolled approach to junctions	0.45

SaferRoads Conference 2017 | opusinternational.com

Top inset demonstrates RAB junctions and junction on a dual carriageway. Bottom inset is an example of junction site categories for a single carriage way with a signalised junction (all approaches in red), give way (middle right red) and hierarchy based (lower 2).

Curves - another challenge

- SCANNER geometric data for ABC roads
- 10 m extents recorded
- Evaluation based on ≥ 50 m extents
- Evaluate over sections of the same road where the road ID changes
 - e.g. A4147/120 and A4147/122

	Single Carriageway	Dual Carriageway
Directions sharing the same Centreline	2 (Increasing <u>AND</u> decreasing)	1 (Increasing <u>OR</u> decreasing)
Classes	3 (S2, S3, Unclassed)	2 (S1, Unclassed)
Complexity	High	Moderate

SaferRoads Conference 2017 | opusinternational.com

Had to analyse single carriageway and dual carriageway separately then bring back together. Single carriageway one to many spatial joins required a check that joined features matched the Road ID (Feature_ID) and Direction (XSECT) to ensure correct matches are analysed and not just any that happen to be nearby. One to Many spatial join used as a one to one may join the incorrect direction and/or road ID, using a one to many give the option to select a subset of data.

Having more categories meant having more steps and more criteria to determine how to class a 10m section in the scheme of a longer extent that could be various sections of interchanging S2/S2/gap, or S1/gap.

No curve (or gradient) data for U roads = no analysis possible for U roads

Curves - assigning site categories

- Raw data: 10 m extents linear referenced from table to network
- (A) Curve radius <500 m and combined length ≥50 m assigned S2
- (B) Curve radius <250 m within (A) assigned S3

SaferRoads Conference 2017 | opusinternational.com

Single Carriageway example (the more complex one)...

- Raw:** The raw data plotted and themed purely on the curve radius values red/S3 <250 m; orange/S2 >250 m and ≤500 m; grey/gap >500 m
- (A):** class full contiguous extents as S2
- (B):** identify extents of S3 based on curve radius criteria (<250 m) alone.

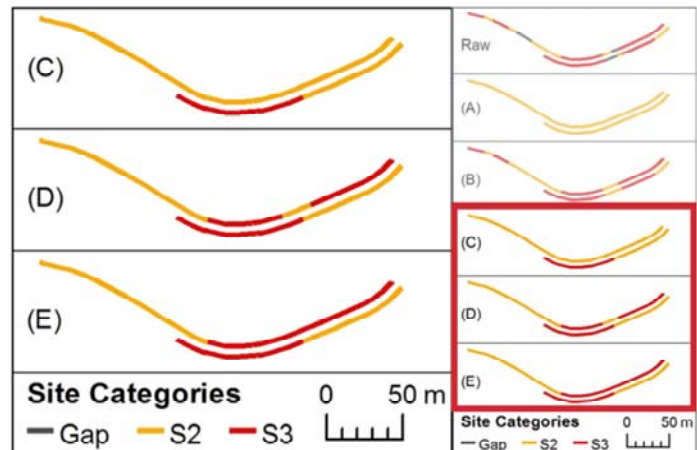

Additional detail

Defining contiguous lengths – take extents of S2 and S3 (based on curve radii alone), single these out, apply 6m buffer to pick up any singular ~10m gap features which may be present between initial S2/S3 10m extents.

Dissolve all adjoining features to determine contiguous lengths and identify length of the contiguous length.

Curves - assigning site categories

- (C) If 70% of an S2/S3 extent is S3 then assign S3 otherwise S2
- (D) Where ≥ 50 m S3 extents are present within S2 class from previous step assign S3
- (E) < 50 m S2 between two ≥ 50 m S3 extents from (D) class as S3
- (F) Gaps < 12 m (neither S2 or S3) between two ≥ 50 m S2/S3 extents added to analysis and steps (A) to (E) repeated

SaferRoads Conference 2017 | opusinternational.com

Single Carriageway example (the more complex one)... (continued)

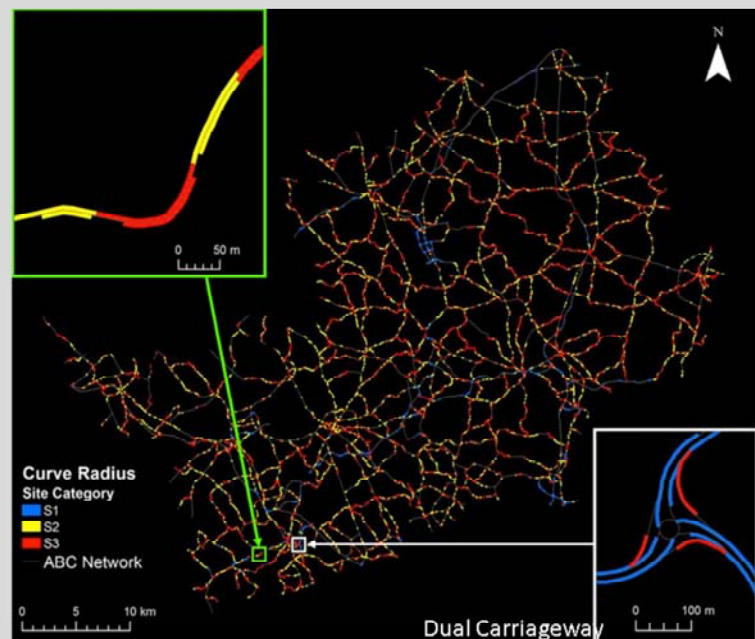

- **(C):** Identify proportion of S2 and S3 per contiguous extent. An arbitrary value of 70% to be met for classification of S3 otherwise default to S2
- **(D):** If contiguous extents of 50 m or more are present within an extent classed as S2 from step (C), class these as S3.
- **(E):** Following step (D), if a S2 extent of < 50 m falls between two S3 extents class this and the S3 extents as S3
- **(F):** if sections of curve radius > 500 m ("gap" sections that are neither S2 or S3) with a length < 12 m are present between two ≥ 50 m contiguous S2/S3 extents include these in the analysis and repeats steps (A) to (E).

Curves

- Extents have to be ≥ 50 m to qualify

Site Category	Description	IL
S1	Dual Carriageway, Radius ≤ 500 m	0.45
S2	Single Carriageway, Radius ≥ 250 m and < 500 m	0.50
S3	Single Carriageway, Bend Radius < 250 m	0.55

SaferRoads Conference 2017 | opusinternational.com

Curve site categories defined for the network.

Top Inset: Single carriageway – top/left polygon extents relate to CL1, bottom/right extents relate to CR1. Note: despite both directions sharing the same centreline the site category extents for each vary.

Bottom Inset: Dual carriageway

• Gradient

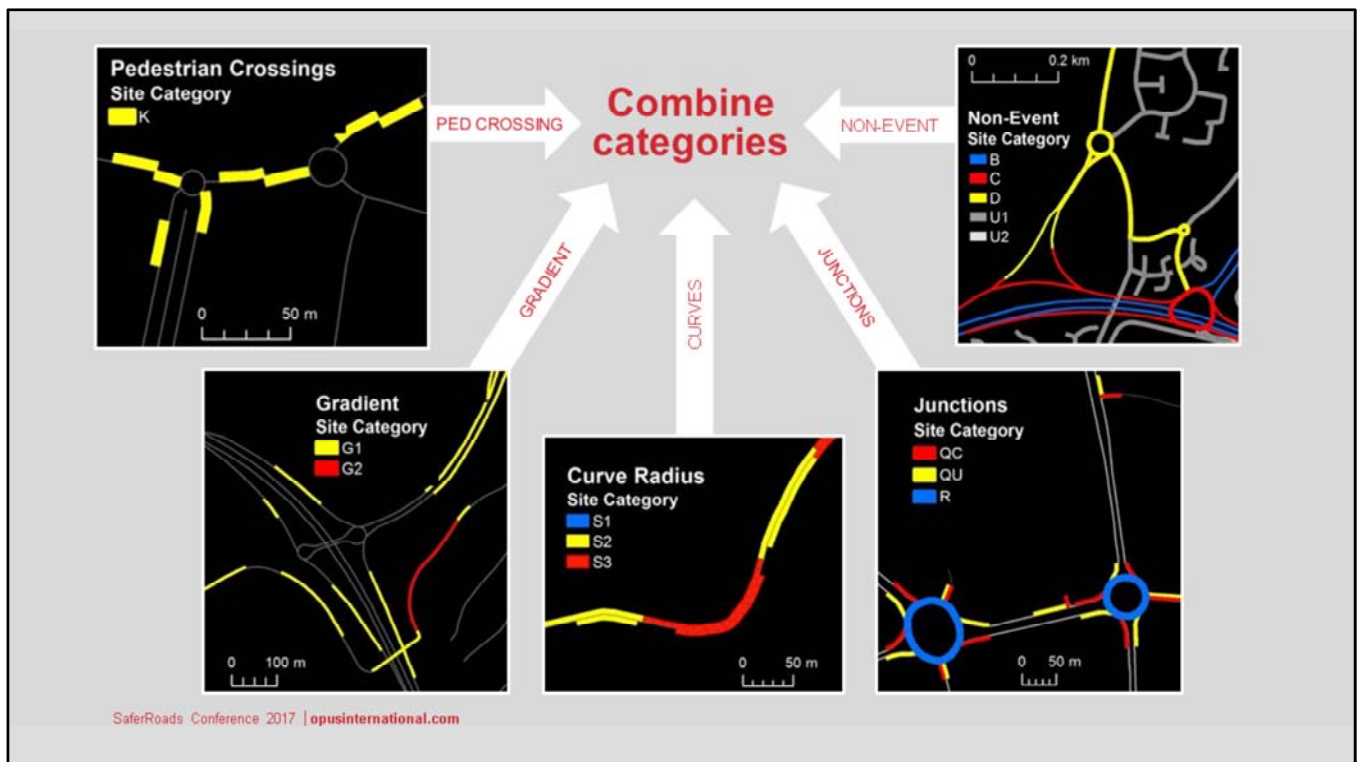

- Similar approach to single carriageway curves
- Extents also have to be ≥ 50 m in length to qualify

Site Category	Description	IL
G1	Gradient 5-10%	0.45
G2	Gradient $\geq 10\%$	0.50

SaferRoads Conference 2017 | opusinternational.com

Similar approach to singles carriageway curves. Main difference is the gradient categories are not unique to carriageway type, so single and dual carriageway can be analysed together instead of being done separately.

Combining all classed network outputs into one output dataset. Need to ensure the datasets have the same fields present, and that these have matching field types and field names. Meant adding and removing some before compiling.

Combining overlapping features from different datasets, and because the feature extents are defined by the extent of the same combination of values the network becomes more fractured as any change in the combination is defined as its own extent.

Through this process there are slithers (e.g. areas $<2\text{m}^2$) and overlaps that need to be ratified, which the model process attempts to do through a stepwise process.

Additional Detail:

On combining, need to have the same data schema i.e. all the fields in the attribute tables need to match in terms of field name and field type (e.g. short integer, double, text, etc.). This meant copies of the outputs were made with several fields dropped and a very few added where these were to be included in the combined output.

Combining datasets through a spatial union results in a chopped up output wherever there is a different combination of values in the row for a feature's attributes than its neighbouring features. As a result small slithers can eventuate.

The polygon features for different roads in each of the datasets can have overlapping

features as a result of the buffer width, so its important to be able to distinguish which features belong to which road and that the features unioned belong to the same Road ID (Feature ID) and direction (XSECT) and retain those while dropping those that don't match.

As the datasets are combined in a stepwise process, there is a ratification process as part of that to identify the really small areas and any overlaps and seek to combine them with the most appropriate feature, before moving on to the next union process. The results of this ratification process has minimised the areas of $<2\text{m}^2$ to just 3 records.

Combined site categories

- 112 combinations
- 71,215 features
- ~60% Non-event
 - ~44% U1 or U2
 - ~17% B, C, or D
- ~40% combination of classes

Site Categories (In Inset)		
 B	 QU, C	 S1, QU, B
 C	 QU, U2	 S2, QU, C
 U1	 R, C	 S3, QC, C
 QC, B	 S1, B	 S3, QU, C
 QC, C	 QC, S1, B	 S3, G1, QU, C
 QU, B	 S3, G1, C	 S3, QC, G1, C

SaferRoads Conference 2017 | opusinternational.com

The majority of the non-events are U1 (29,056 = 41% of all classes) and to a lesser degree U2 (2,058 = 3% of all classes).

The main focus was on the A/B/C roads, which had more complete data coverage, higher speed limits, and likely greater traffic volumes

Analysis on U roads was limited. Curve and gradient data did not cover U roads. Can't rely on hierarchy in junctions consisting only of U roads where there are no records in the spatial data of any controls meant these would be more difficult to determine which approaches are controlled and which are not.

Combined ILs

- Theme by max IL for each feature

IL	Site Categories
0.55	S3
0.50	G2, K, QC, S2
0.45	G1, QU, R, S1
0.40	C, U2
0.35	B, D, U1

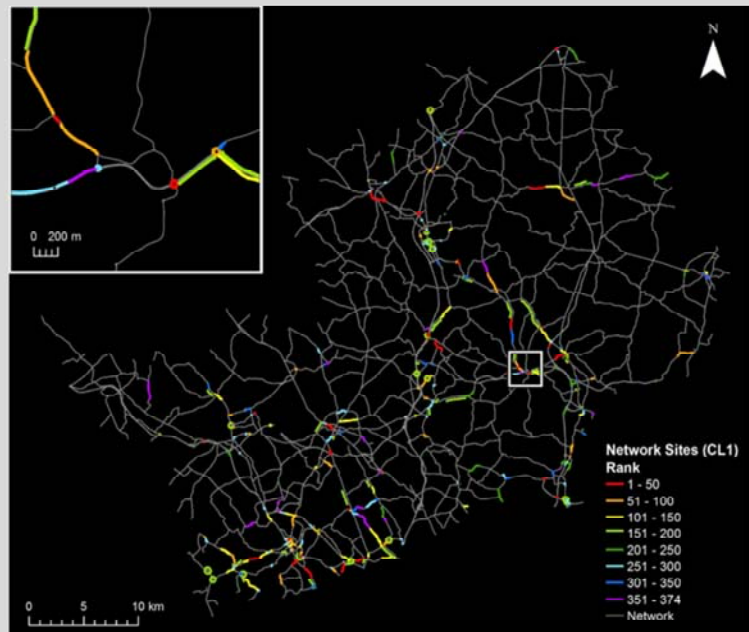

SaferRoads Conference 2017 | opusinternational.com

Application

- HCC compared skid resistance data with ILs
 - Resulted in many sections requiring potential attention
- Focus on >25 m and skid resistance below IL
- Sections ranked for treatment based on:
 - Crash history
 - Road class
 - Speed limit
 - AAWT
 - Difference from IL

SaferRoads Conference 2017 | opusinternational.com

AAWT = Annual Average Weekday Traffic

AAWT = Annual Average Weekday Traffic

IWP = Integrated Works Programme

Application

- Identified lengths compared with the HCC Integrated Works Programme (current and future) to identify efficiencies for timing of the skid resistance works
- Additional uses of model outputs being applied in other road safety spatial analysis applications

SaferRoads Conference 2017 | opusinternational.com

AAWT = Annual Average Weekday Traffic
IWP = Integrated Works Programme

• Conclusions

- Engineering approach to deliver skid resistance for network aligned with road user needs, prioritisation of risk, and budgetary constraints
- Use of GIS to apply the Strategy to the network has been complex
- Key points
 - Skid resistance as a fundamental component of road safety
 - Use of measured skid resistance with purpose to enhance skid resistance
 - Appropriateness of adopted skid resistance standards
 - Spatial representation dependent on suitable data

SaferRoads Conference 2017 | opusinternational.com

- Strategy which meets needs
- Strategy applied in GIS, complex but valuable.
- Skid resistance important to road safety
- Measure to enhance
- Appropriate standards
- Spatial output reliant on good data

• Acknowledgements

- The authors acknowledge with thanks:
